Univ. of Arkansas  
Fayetteville, AR**

G. Hofmann

# What exactly do we want to achieve?

- Monitoring program to estimate system state and related variables
  - Status will dictate how to direct conservation
  - Compare with model-based predictions to understand dynamics

# 3 State-level Variables . . .

## 1. Community – multiple species

- State var. = spp. richness

## 2. Patch – single species

- State var. = occupancy

## 3. Population – single species

- State var. = abundance

$$E( C ) = Np$$

**$E( C )$  = expected count**

**$N$  = true abundance**

**$p$  = detectability**

$$\hat{N} = C / \hat{p}$$

# Logistically feasible, unbiased estimator??

Occupancy rate = proportion of sites a  
spp. occupies

# Occupancy Rate Estimation

- Presence/absence surveys
  - Detection/Non-detection
  - Reduced effort
- Does not require large sample sizes
  - Most other techniques are data hungry
  - Ideal for rare/elusive spp. (lots of 0's)

# Occupancy Rate Estimation

$$\hat{\Psi} = \frac{\hat{x}}{S}$$

$\hat{\Psi}$  = Estimate of occupancy

$\hat{x}$  = Estimate of occupied sites

$S$  = Total number of sites

**Probability of detection  
(i.e., not all absences are “true” absences)**

# Objectives

- Spp. occurrence and distributions
- Habitat use
- Heterogeneous detection probabilities

# Objectives (cont'd)

- Rates of co-occurrence with other spp.
- Current abundance levels (Royle and Nichols 2003)
- Recommendations for long-term monitoring

# Abundance Models (Royle and Nichols 2003)

- Heterogeneous  $p$  can be a function of varying  $N$  levels among sites
  - $p$  can be used to characterize  $N$

vs.

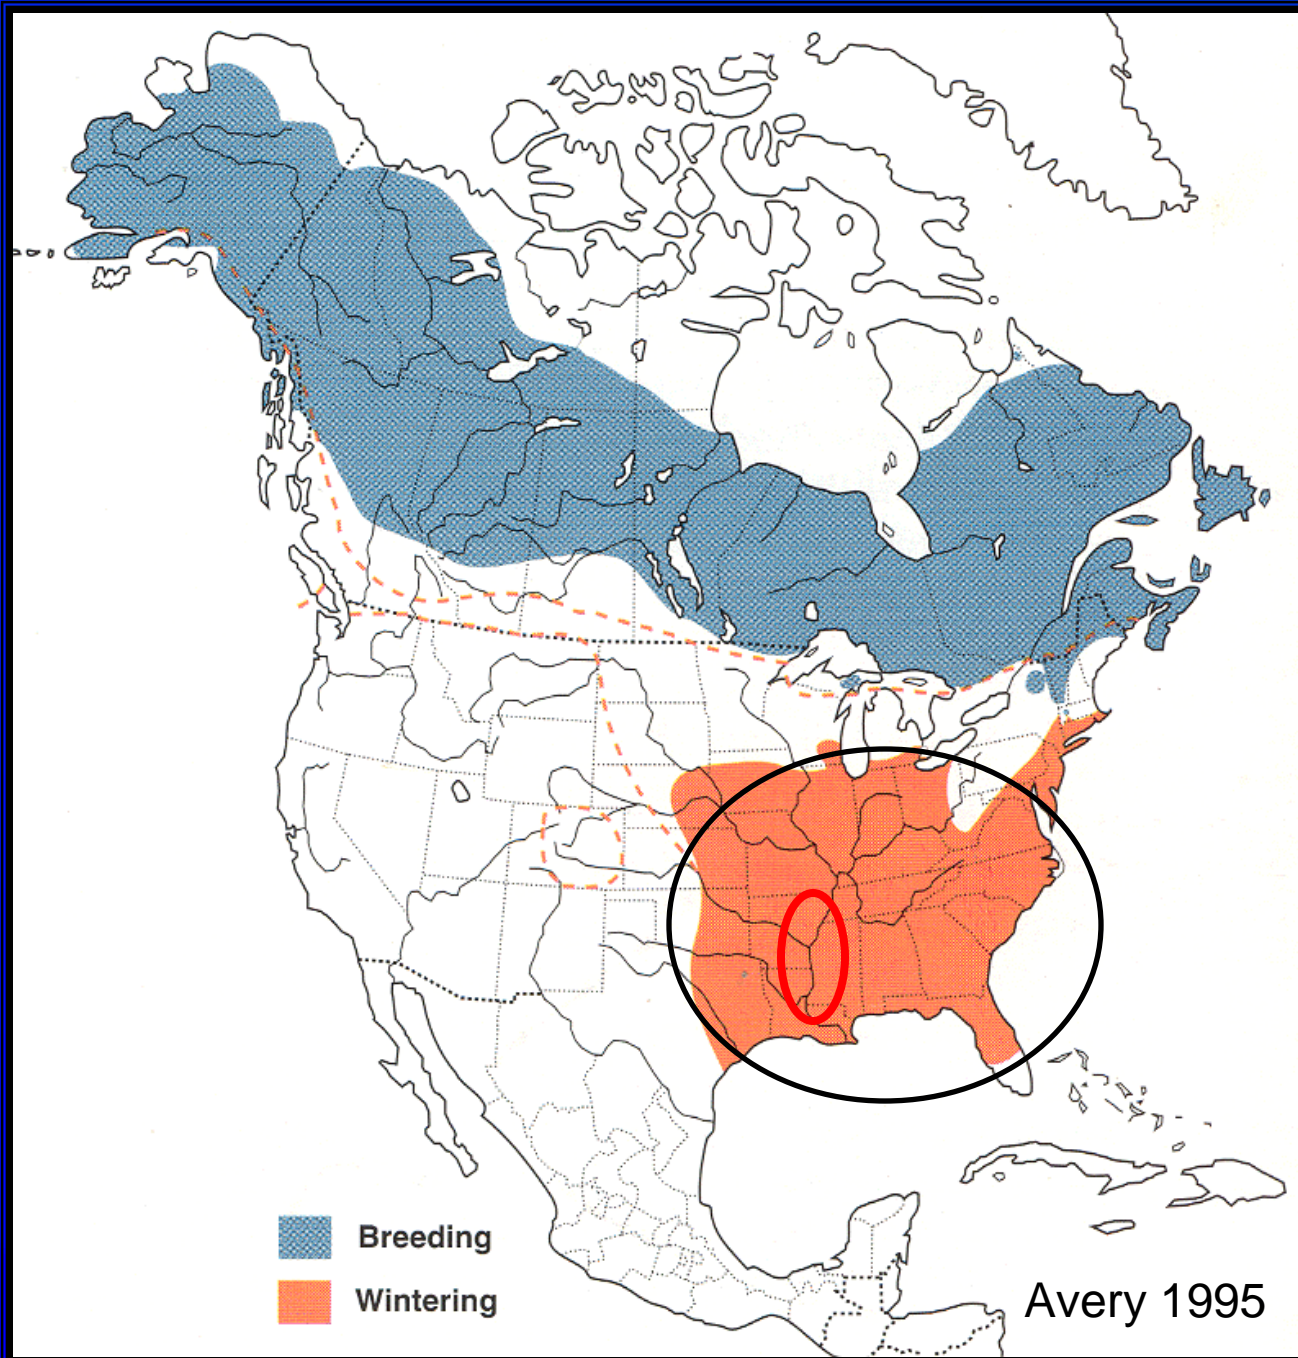

# Abundance Models (Royle and Nichols 2003)

## Assumptions:

- site-specific  $N$  has a Poisson distribution with mean  $\lambda$ 
  - *i.e., bird distributions in space follow Poisson*
- detection of individuals is independent

**If assumptions are met,  $\lambda$  = density**

**Birds spread out on breeding grounds but flock on wintering grounds – thus, estimation of wintering populations**

# Sampling Design

Randomly selected sites surveyed during 2 seasons: January and February

## Recorded:

1. Presence/absence and #'s
2. Other spp.
3. Habitat measurements (local and landscape level)
4. Weather

# Habitat Measurements

- Local
  - Tree density, canopy cover, ground cover
- Landscape
  - Forest age, forest type, % urbanization, distance to nearest body of water

# Other variables . . .

- Air temp
  - May dictate diet
- Presence/absence of other birds (i.e., Icterids, startlings, robins)
  - To estimate co-occurrence rates

Johnson Mill

© Marie Read

# 2006 Field Season (Pilot Year)

- $\geq 4$  surveys per season at 79 sites
  - 52 in forests
  - 17 in fields

# 2007 Field Season

- $\geq 5$  surveys per season at 115 sites
  - 68 sites in forests
  - 47 sites in fields

# Preliminary Results

- Program PRESENCE (MacKenzie et al. 2002)
- Still working on a candidate set of models incorporating habitat and landscape variables

**Changes from year-to-year:**

- Water levels
- Climatic differences

**Evaluate long-term temporal patterns!!**

- **300 sites on DOD and NWR lands in southeast**
  - A region thought to have fewer Rusties
- **2 visits per site**

# Conclusion

**Logistically  
feasible state  
variable for  
monitoring Rusty  
Blackbird  
populations  
temporally  
and/or spatially!**
